

WEB DATA EXTRACTION & PRODUCT CATALOGUE

Client-Ready Data Extraction Project

What I did

I extracted the full product catalogue from a publicly accessible WooCommerce API and turned the raw JSON response into a clean, usable dataset.

The extraction covered **324 products across 33 API pages**. I handled pagination, request timeouts and temporary errors, while keeping the original API responses intact for traceability.

What I cleaned

The raw API data contained nested fields such as prices, categories and brands. I converted these into a structured table, converted the API's price values into readable currency amounts, standardized text fields, and removed the unusable **Brands** field because it contained no populated values.

Quality checks

Before delivery, I checked:

- **324** products collected
- **324** unique Product IDs
- **0** duplicate products
- **0** failed extraction pages
- No negative prices or review counts
- Ratings within the expected 0–5 range
- Product names, SKUs, currencies and URLs present
- Price consistency between sale and regular prices

Final delivery

The cleaned catalogue contains **324 records and 12 business-ready fields**, delivered in both **Excel and CSV**, with the original JSON and extraction log included for reference.

Tools: Python · Requests · Pandas · JSON · Google Colab

Workflow:

API → Extract → Paginate → Transform → Clean → Validate → Deliver
